

This fact sheet answers the most frequently asked health questions (FAQs) about cesium. For more information, call the ATSDR Information Center at 1-888-422-8737. This fact sheet is one in a series of summaries about hazardous substances and their health effects. It is important you understand this information because this substance may harm you. The effects of exposure to any hazardous substance depend on the dose, the duration, how you are exposed, personal traits and habits, and whether other chemicals are present.

HIGHLIGHTS: Exposure to stable or radioactive cesium occurs from ingesting contaminated food or drinking water or breathing contaminated air. High levels of radioactive cesium can cause nausea, vomiting, diarrhea, bleeding, coma, and even death. This may occur after nuclear accidents or detonation of atomic bombs. Stable (non-radioactive) cesium has been found in at least 10 of the 1,585 National Priority List (NPL) sites identified by the Environmental Protection Agency (EPA). Radioactive cesium has been found in at least 22 of the 1,585 NPL sites identified by the EPA.

What is cesium?

Cesium is a naturally occurring element found combined with other elements in rocks, soil, and dust in low amounts. Naturally occurring cesium is not radioactive and is referred to as stable cesium. There is only one stable form of cesium naturally present in the environment, ¹³³Cs (read as cesium one-thirty-three).

Nuclear explosions or the breakdown of uranium in fuel elements can produce two radioactive forms of cesium, ¹³⁴Cs and ¹³⁷Cs. Both isotopes decay into non-radioactive elements. ¹³⁴Cs and ¹³⁷Cs generate beta particles as they decay. It takes about 2 years for half of ¹³⁴Cs to give off its radiation and about 30 years for ¹³⁷Cs; this period of time is called the half-life.

What happens to cesium when it enters the environment?

- ☐ Stable cesium in air can travel long distances before settling to the ground or water.
- ☐ Most cesium compounds dissolve in water.
- ☐ In most soils, most cesium compounds are very soluble.
- ☐ Cesium binds strongly to most soils and does not travel far below the surface of the soil.
- ☐ Radioactive decay is the only way of decreasing the amount of ¹³⁴Cs and ¹³⁷Cs in the environment.

How might I be exposed to cesium?

- ☐ You can be exposed to low levels of stable or radioactive cesium by breathing air, drinking water, or eating food containing cesium.
- ☐ Food and drinking water are the largest sources of exposure to cesium.
- ☐ You can be exposed to radioactive cesium if you eat food that was grown in contaminated soil.
- ☐ Working in industries that process or use natural cesium or cesium compounds.
- ☐ Living near uncontrolled radioactive waste sites containing cesium.

How can cesium affect my health?

It is highly unlikely that you would be exposed to high enough amounts of stable cesium to cause harmful health effects. Laboratory animals given very large amounts of cesium compounds showed changes in behavior, such as increased or decreased activity.

Exposure to large amounts of radioactive cesium can damage cells in your body from the radiation. You might also experience acute radiation syndrome which includes nausea, vomiting, diarrhea, bleeding, coma, and even death in the case of very high exposures.

ToxFAQs™ Internet address is <http://www.atsdr.cdc.gov/toxfaq.html>

How likely is cesium to cause cancer?

There are no studies regarding non radioactive cesium and cancer. There are no human studies that specifically associate exposure to radioactive cesium with increased cancer risk.

Because radioactive cesium emits ionizing radiation, carcinogenic effects similar to those observed in Japanese survivors of the atomic bombing incidents might be expected among individuals acutely exposed to very high levels of radiation from a radioactive cesium source.

Rats exposed to high doses of radiation from ^{137}Cs had increased risk of mammary tumors. Older rats seemed more resistant than younger ones.

How can cesium affect children?

Children can be affected by cesium in the same ways as adults. Infants born to atomic bomb survivors exposed to high doses of ionizing radiation while pregnant, showed later signs of decreased mental abilities.

Exposure to the radiation from radioactive cesium has caused birth defects in animals.

How can families reduce the risk of exposure to cesium?

Since cesium is naturally found in the environment, we cannot avoid being exposed to it. However, these relatively low amounts do not warrant immediate steps to reduce exposure. In the unlikely case that you are exposed to high levels of radioactive cesium because of accidental release at a nuclear plant or a nuclear weapon has been detonated, follow the advice of public health officials who will publish appropriate guidelines for reducing exposure.

Is there a medical test to show whether I've been exposed to cesium?

Everyone has small amounts of cesium in their bodies. There are special laboratory tests to measure cesium in blood, urine, feces, and tissues. These tests are most useful for people exposed to high levels, but will not predict whether harmful effects will occur.

If a person has been exposed to radioactive cesium, special tests can be used to measure levels of radiation in blood, feces, or urine. However, it is difficult to determine if a person has been exposed only to external radiation from radioactive cesium.

Has the federal government made recommendations to protect human health?

The EPA has established a maximum contaminant level of 4 millirem per year for beta particles and photon radioactivity for man-made radionuclides (including radioactive cesium).

The National Institute for Occupational Safety and Health (NIOSH) recommends a limit of 2 milligrams of cesium hydroxide per cubic meter of air (2 mg/m^3) as an average for a 10-hour workday, 40-hour workweek.

The Nuclear Regulatory Commission (NRC) has set occupational air limits of $0.04 \mu\text{Ci/m}^3$ for ^{134}Cs and $0.06 \mu\text{Ci/m}^3$ for ^{137}Cs . NRC also set a limit intake of 0.1 mCi for ^{134}Cs and 0.2 mCi for ^{137}Cs for on-the-job exposure.
